Freed, PhD2,31 Deployment Health Clinical Center, Defense Centers of Excellence for Psychological Health and Traumatic Brain Injury, Silver Spring, MD; <sup>2</sup>Uniformed Services University of the Health Sciences, Department of Psychiatry, Bethesda, MD; 3Currently at National Institute of Mental Health, Bethesda, MD.

# INTRODUCTION

Brief screening instruments are often used in primary care and high-risk settings to screen for a variety of mental health disorders, including PTSD. The 4-item PC-PTSD (Primary Care PTSD Screen) is currently used in many settings to screen for PTSD (i.e., Military Health System, Veterans Affairs) using a two-stage approach. The two-stage approach screens the general population with a brief screener, and only patients who screen positive are subsequently administered a lengthier screening assessment. Population-level screening necessitates a validated PTSD screening tool that minimizes patient and provider burden in busy primary care clinics.

Building upon prior work by this team (Gore et al., 2008), we used a data-driven approach to refine and test two versions of a Single-Item PTSD Screener (SIPS A and SIPS B) for use in military primary care settings.

# AIMS

- 1. Examine psychometric properties of two versions of a single-item PTSD screen (SIPS A and SIPS B), relative to the 4-item PC-PTSD and the 17-item PCL-C (civilian version)
- 2. Compare operating characteristics to determine optimal cut points for clinical use of the SIPS A and SIPS B

# METHODS

### Sample

- 437 participants were recruited from Walter Reed National Military Medical Center Primary Care Clinic (WRNMMC) waiting room.
- Strategic, representative sampling technique
- 10% PTSD positive (based on MINI-PTSD (Mini International Neuropsychiatric Interview))

### Measure development

- SIPS A: Face-valid, summary question
  - o Developed through strategic refinements to the original SIPS.
- SIPS B: Symptom-driven question
  - o Based on PCL-C items determined to have strongest predictive power for PTSD diagnosis through secondary analysis of original SIPS study data.
- Candidate SIPS questions were refined and selected through expert consult and brief cognitive interviews with patients.

### Procedures (Figure 1)

- Consented participants completed all study measures.
- Completed MINI-PTSD diagnostic interview with study staff member.
- · Completed mailed follow-up packet of PTSD screens.

### TABLE 1 – SAMPLE CHARACTERISTICS

Demographics N = 437		% or Mean (SD)			Clinical Indicators N = 437
Age		43.7 (13.6)	l		PC-PTSD

# **Eligibility Criteria:** Age: 18 - 65 Measures:

PHO. AUDIT-C. VA-TBI. SF-12 Numeric Pain Rating Scale

Consent +

# Diagnostic Interview (0-2 days after Consented Packet) n = 413

Eligibility Criteria: Completed Consented Packet

Measures: MINI-PTSD

## Mailed Re-Screen (7 days after Diagnostic Interview) n = 358

Eligibility Criteria: Completed Diagnostic Interview

Measures: SIPS-A. SIPS-B. PC-PTSD, PCL-C

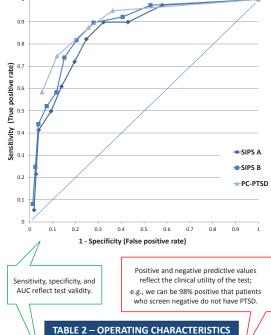

# **RESULTS**

- Binomial logistic regression was applied to construct ROC curves for SIPS A, SIPS B, and PC-PTSD (Figure 2).
- Chi-square comparisons of areas under the curves (AUC) determined equivalence among the SIPS A, SIPS B, and PC-PTSD:
- SIPS A and SIPS B did not differ statistically (X<sup>2</sup> = 1.35, p-value = 0.25; AUC = 0.85 vs. 0.88). SIPS B and PC-PTSD did not differ statistically (X<sup>2</sup> = 0.25, p-value = 0.62; AUC = 0.88 vs. 0.89). o SIPS A and PC-PTSD did not differ statistically (X2 = 1.82, p-value = 0.18; AUC = 0.86 vs. 0.89).
- The PCL-C performed better than the PC-PTSD ( $X^2 = 3.83$ , p-value = 0.05; AUC = 0.93 vs. 0.89), SIPS A ( $X^2 = 9.94$ , p-value = 0.002; AUC = 0.93 vs. 0.86), and SIPS B ( $X^2 = 4.82$ , p-value = 0.03; AUC
- · Evaluation of psychometric data and chi-squares based on a two-stage screening approach (SIPS A/B > PCL-C) identified the optimal cut point for SIPS A and B = 3 to balance sensitivity/specificity and positive/negative predictive values (See Table 2 for operating characteristics).
- Multivariate binomial logistic regression analyses determined the PC-PTSD better predicted PTSD compared to the SIPS A and SIPS B ( $X^2 = 171.889$  vs. 228.216, p < 0.01;  $X^2 = 171.889$  vs. 215.124, p
  - o Additional predictors (e.g., age, sex, military status) will be used to control for bias and identify true performance.

PPV = Positive predictive value; NPV = Negative predictive value; DE = Diagnostic efficiency.

# CONCLUSIONS

- The Single-Item PTSD Screener (SIPS) performs similarly to the already-in-use 4-item PC-PTSD in a DoD primary care sample, but not as well as the 17-item
- If used as the initial screener in a two-stage screening process, a cut point of 3 on the SIPS A or B is appropriate for identifying patients who should undergo further assessment for PTSD.
- Preliminary findings suggest the PC-PTSD may predict PTSD better than the SIPS
- As a whole, these findings suggest that the SIPS A and SIPS B are promising ultra-brief screening instruments for military primary care.
